

## REMARKS

Entry of the amendments to the specification and claims, as amended by way of Annexes to the International Preliminary Examination Report for PCT/EP2004/013263, before examination of the application in the U.S. National Phase is respectfully requested.

If there are any questions regarding this Preliminary Amendment or the application in general, a telephone call to the undersigned would be appreciated since this should expedite the prosecution of the application for all concerned.

If necessary to effect a timely response, this paper should be considered as a petition for an Extension of Time sufficient to effect a timely response, and please charge any deficiency in fees or credit any overpayments to Deposit Account No. 05-1323 (Docket # 095309.57890US).

Respectfully submitted,

A handwritten signature in dark ink, appearing to read "Gary R. Edwards". The signature is fluid and cursive, with the first name "Gary" and last name "Edwards" clearly distinguishable.

## ABSTRACT OF THE DISCLOSURE

A vehicle control device ~~with a unit (10) which is equipped so as to activate~~  
activates an ~~especially continuously~~ adjustable drive unit  $[(11)]$  of a motor  
vehicle  $[(12)]$  dependent upon at least one control signal,  $(\alpha, \alpha_{virt})$ , ~~and at least~~  
~~in one phase (T) to create~~ In a constant driving mode, a virtual control signal is  
created  $[(\alpha_{virt})]$  and used instead ~~to use a~~ of the real control signal,  $[(\alpha)]$  for  
activating the drive unit,  $[(11)]$ . ~~It is suggested that the unit (10) be equipped~~  
~~so as to activate the drive unit (11) at least in a constant driving mode dependent~~  
~~upon the virtual control signal  $(\alpha_{virt})$ .~~

(Fig. 1).

Device with a unit for activating an adjustable drive unit of a motor vehicle

## BACKGROUND AND SUMMARY OF THE INVENTION

[0001] This application claims the priority of German patent document 103 60 640.8, filed December 23, 2003 (PCT International Application No. PCT/EP2004/013263, filed November 23, 2004), the disclosure of which is expressly incorporated by reference herein.

[0002] The invention concerns a device with a unit for activating an adjustable drive unit of a motor vehicle ~~according to the specifications of Claim 1.~~

[0003] ~~From the patent~~ Published U.S. Patent Application No. 2001/0056009 A1 discloses a device with a unit ~~is known~~ which is equipped so that an ~~especially continuously~~ adjustable drive unit of a motor vehicle is activated ~~independently of~~ dependent upon at least one control signal, which represents an adjustable angle of a gas pedal. At ~~At~~ [[and at]] least in one phase, ~~to produce a virtual control signal is produced and [[to use]] used instead of the [[one]] real control signal, for activating the drive unit. The activation is done as a function of a control signal which represents an adjustable angle of a gas pedal. The unit governs in the~~ In this phase, propulsion of the ~~a propelling force of a motor vehicle containing the device so that a desired propelling force is adjusted,~~

~~so that by which~~ a constant separation is maintained to a vehicle traveling in front of the motor vehicle ~~is maintained~~.

[0004]        [[The]] One object of the invention is ~~based on the task of providing~~ to provide a generic device which ~~converts~~ implements a constant travel desire of the driver, in a comfortable [[way.]] manner.

[0005]        This and other objects and advantages are achieved by the control arrangement according to the invention, ~~The invention proceeds from a device with a unit~~ which includes a unit that is equipped so that an (especially continuously) adjustable drive unit of a motor vehicle is activated dependent upon at least one control signal, and ~~to produce in~~ at least [[in]] one phase, a virtual control signal is generated and used instead ~~to use of~~ a real control signal for activating the drive unit. According to the invention, ~~It is suggested that~~ the unit [[be]] is equipped so that the drive unit is activated (at least in a constant drive mode, in which the unit generates a constant driving force of the motor vehicle through a suitable choice of the control signal) dependent upon the virtual control signal. In this manner, ~~Thereby it can advantageously be achieved that~~ in the constant drive mode, [[no]] small deviations from the actual control signal[[,]] (*i.e., the signal* produced by the driver of the motor vehicle, indicating [[of]] a course of the control signal desired by the driver of the motor vehicle and anticipated by the unit) do not lead to an adjustment ~~process~~ of the drive unit, and ~~indeed especially also then~~ when the deviations ~~have an~~ are infrequent ~~proportion~~. [[No]] Small deviations of the control signal from the

desired course ~~can be because of a~~ based on the constant drive desire of the driver ~~are acknowledged~~ can be recognized as unwanted and ~~[[are]]~~ ignored, ~~whereby~~ so that the driver can have a peaceful comfortable driving feeling experience. Moreover by a suitable choice of a course of the virtual control signal, advantages relative can be achieved with regard to ~~[[a]]~~ both fuel consumption in the constant drive mode, and ~~[[a]]~~ long service life of the drive unit ~~can be achieved~~. ~~This can be carried out mechanically precisely by~~ By anticipating the an ~~anticipation of a~~ time course of the control signal determined by the constant drive desire of the driver, this can be carried out more precisely using ~~[[by]]~~ the virtual control signal ~~as this~~ than is possible ~~[[to]]~~ by a driver.

[0006] A time course of a control signal desired by the driver can be ~~able to~~ be anticipated reliably in the constant drive mode especially simply and advantageously. An especially simple control and/or regulating logic of the drive unit can be achieved ~~[[when]]~~ if the constant drive mode differs from other operating modes only in the use of the virtual control signal instead of the real control signal. An operating mode of the motor vehicle in which, ~~the unit sets up~~ by a suitable choice of the control signal, the unit sets up a substantially the ~~essentially~~ constant propelling power of the motor vehicle, should ~~shall~~ be designated as constant drive mode. Thereby it can come to an acceleration or to a ~~slowdown~~ deceleration of the motor vehicle dependent upon a driving resistance.

[0007] The drive unit can be, for example, ~~constructed as~~ a motor ~~for~~ ~~example~~ with adjustable throttle valves, ~~[[as]]~~ a drive, ~~[[as]]~~ a clutch, or ~~[[as]]~~

another known adjustable unit ~~appearing to the specialist as meaningful~~ with an influence on the drive train [[cord]] of the motor vehicle. Due to the sensitivity of such units relative to small fluctuations in the control signal there are special advantages relative to comfort [[when]] if the drive unit of the motor vehicle is constructed as a continuous operation of a motor vehicle continuously variable. The real control signal can be given by any characteristic magnitude with an influence upon an activation of the drive [[cord,]] train, as known to those skilled in the art, which is ~~appearing as meaningful to the specialist,~~ adjustable by a driver. Due to [[the]] its direct effect, however, the ~~solution according to the~~ invention is especially advantageously adjustable [[when]] if the control signal represents an adjustment of a gas pedal or an adjustment angle of a gas pedal.

[0008] The unit can be made as a single part or [[a]] multiple [[part]] parts with the drive unit. By “provided” in this connection “laid out” and “equipped” should also be understood.

[0009] ~~In this connection a~~ The control signal ~~should be~~ designated as “virtual” ~~when it is~~ should be mechanically produced and at least ~~extensively~~ substantially independent of [[an]] the actual course of the real control signal produced by the driver. At least a characteristic magnitude[[,]] (for example an rpm of the drive unit) [[,]] should be uncoupled in the phase of the real control signal and be determined by the virtual control signal.

[0010] The virtual control signal can be produced by the unit itself or by a sub-unit, for example a computer unit.

[0011] An especially [[calm]] quiet driving feeling sensation in the constant driving mode can be achieved [[when]] if the unit is provided for determining a constant virtual control signal ~~is provided~~. There are however also other time courses of the virtual control signal, that are known to those skilled in the art, ~~appearing as meaningful to the specialist~~ which may be considered.

[0012] If the unit is ~~equipped for determining~~ configured to determine the virtual control signal dependent upon a real control signal at [[the]] a switch on point of the constant drive mode, advantageously an adaptation of the constant drive mode to the circumstance leading to the switching on of the constant drive mode can be achieved.

[0013] If the virtual control signal ~~to the switching on point~~ is equal to the real control signal at the switching on point, ~~it can advantageously be achieved that the switch on point in time can become barely at least can hardly be perceptible by the driver.~~ [[It]] In particular, it ~~can advantageously be avoided that the driver gets a feeling of independence~~ lack of control of the motor vehicle.

[0014] If the unit for switching on and switching off the constant drive mode ~~dependently provided with a~~ is dependent upon the time course of a real control signal, ~~it can advantageously be achieved that the driver by means of the~~

~~control signal~~ can exercise a full control over the motor vehicle by means of the control signal. Thereby ~~it can be achieved that~~ an acceleration or braking desire of the driver can be ~~[[is]]~~ acknowledged ~~[[when]]~~ if the unit is equipped to switch off the constant drive mode when the real control signal ~~exits for an~~ exceeds a set interval. ~~[[The]]~~ Advantageously, the interval can ~~thereby—especially~~ advantageously be adaptable to ~~[[a]]~~ the long or medium term driving behavior of the driver, and ~~be determined in its average point~~ can be determined by an average point of the real control signal.

[0015] If the unit is equipped ~~for switching to switch~~ off the constant driving mode when a rate of change speed of the real control signal ~~cuts out for an interval~~ exceeds a preset range, it is possible to achieve an especially fast reaction of the unit to an acceleration or braking wish of the driver—~~can advantageously be achieved.~~

[0016] Analogous criteria for switching off the constant driving mode can advantageously be formulated relative to ~~[[a]]~~ the time course of ~~[[a]]~~ the speed of the motor vehicle and/or a driving resistance.

[0017] If the unit for activating the motor vehicle engine is ~~provided~~ dependent upon a discontinuous control signal upon switching off the constant driving mode, ~~it can advantageously be achieved that the driver is imparted~~ can experience an especially spontaneous driving feeling. ~~Especially when the~~ In particular, if a unit for activating a continuous drive is provided, it can be

~~achieved that the unit in recognizing~~ recognize an acceleration desire, ~~and~~ abruptly ~~reduces~~ reduce a translation whereby a torque reserve of a motor is abruptly increased, which [[. This]] is perceived by the driver as spontaneous downshifting. There are also however arrangements of the invention to be considered in which the unit smoothes the discontinuity in a way, for example, that is dependent upon a driver's profile.

[0018] Other objects, advantages and novel features of the present invention will become apparent from the following detailed description of the invention when considered in conjunction with the accompanying drawings.

#### BRIEF DESCRIPTION OF THE DRAWINGS

~~Further advantages are given by the following illustration description. The figures represent an implementation example of the invention. The figures, the claims, and the description contain several features in combination. The specialist will also consider these features individually and combine them into additional purposeful combinations.~~

They show:

[0019] Fig. 1 [[. A]] shows a motor vehicle with a continuously adjustable variable drive unit, a gas pedal and a unit for activating the drive unit dependent upon a control signal from the gas pedal; [[.]]

[0020] Fig. 2 [[. A]] is a flow chart of a program that illustrates a process for activating the drive unit from Figure 1, in a constant driving mode and in a normal mode; [[.]]

[0021] Fig. 3 [[. A]] is a decision diagram of the program from process in Figure 2; [[.]] and

[0022] Fig. 4 [[. a]] is a graphic depiction of the time [[flow]] variation of a real control signal and a virtual control signal.

### DETAILED DESCRIPTION OF THE DRAWINGS

[0023] Figure 1 shows a motor vehicle 12 with a unit 10 which ~~is equipped for activating~~ can activate an adjustable drive unit 11 (formed in the illustrated example as a continuously variable drive), dependent upon a real control signal  $\alpha$  and upon a virtual control signal  $\alpha_{virt}$ . The unit 10 is equipped [[so as]] to recognize a constant drive desire of a driver, and to switch on a constant drive mode supporting this desire dependent upon a time course of the real control signal  $\alpha$  while during a phase T, and to switch it is switched on and switched off (Fig. 4) [[and]] at the end of the phase T. The real control signal  $\alpha$  represents an adjustment angle of a gas pedal 13, includes a sensor integrated into the gas pedal 13, and can read the unit 10 over a CAN interface from a CAN bus of the motor vehicle 12. Moreover the unit 10 is so designed as to acquire additional characteristic values of the motor vehicle 12, for example [[a]] velocity v, [[an]]

acceleration, ~~[[an]]~~ engine rpm, and a throttle valve angle of a motor vehicle, through the CAN interface. A computer unit 14 of the unit 10 is equipped to calculate a driving resistance from the acceleration, the throttle valve angle, and the velocity  $v$  and to issue this as a characteristic value for a highway rise  $m$ .

[0024] ~~The unit 10 is designed so that the~~ program for recognizing a constant driving desire ~~represented in (Figure 2) as a flow chart~~ sets a control bit  $c_b$  to 1 upon recognizing a constant driving desire, and otherwise to 0. After an initialization 15, ~~the unit 10 determines~~ in an interval determination step 16 the unit 10 determines the width and centers of gravity of intervals  $I_a$ ,  $I_v$ ,  $I_{\alpha'}$  ~~[[in]]~~ within which the speed  $v$  and the control signal  $\alpha$  and a change velocity  $\alpha'$  of the control signal  $\alpha$  must necessarily vary ~~so that in order for~~ the unit 10 ~~recognizes to recognize~~ the occurrence of a constant driving wish. The centers of gravity of the intervals  $I_a$ ,  $I_v$ ,  $I_{\alpha'}$  are an equalizing means over a pre-adjusted time interval of the respective values  $\alpha$ ,  $\alpha'$ ,  $v$  and the width of the intervals  $I_a$ ,  $I_v$ ,  $I_{\alpha'}$  are determined by the variance of the respective values  $\alpha$ ,  $\alpha'$ ,  $v$ . In a threshold value determination (step 17) ~~[[the]]~~ threshold values ~~[[are]]~~ stored in a memory unit of the unit 10, as well as ~~and indeed~~ a maximum value  $m_{\max}$  and minimum speed  $v_{\min}$  are read out.

[0025] In a decision block 18 (which is represented in detail in Figure 3), ~~[[4,]]~~ the unit 10 checks whether constant driving conditions are met. If ~~this is the case so~~, the unit increments a time measurement counter. If not all constant driving conditions are met, in a step 20 the unit 10 ~~in a step 20~~ sets the time

measurement counter and the control bit  $c_b$  to 0. After the incrementing of the time measurement counter the unit 10 checks  $[[in\ a]]$  (step 19) whether the time measurement counter has exceeded a stored critical value. Since the decision block 18 will always run in elementary time intervals, the value of the time measurement counter is proportional to the duration  $\tau'$  over which time all constant driving conditions are met. If the duration  $\tau'$  is longer than an applicable value  $\tau$ , in a step 21 the unit 10 sets the control bit  $c_b$  ~~in a step 21~~ to 1, sets the virtual control signal  $\alpha_{virt}$  to the actual value of the control signal  $\alpha$  and switches the constant driving mode on, whereby the phase T begins. If the time period  $\tau'$  is shorter than the value  $\tau$  then the unit 10 sets the control bit  $c_b$  in step 20 to 0. In an output step 22 the unit 10 finally outputs the control bit  $c_b$ .

**[0026]**     As shown in Figure 3, in  $[[In]]$  the decision block 18, the unit 10 checks in a first step 23 whether the control signal  $\alpha$  lies in the interval  $I_\alpha$  and whether the change speed  $\alpha'$  of the real control signal  $\alpha$  lies  $[[in]]$  within the corresponding interval  $I_{\alpha'}$  (Fig. 3). ~~If this is the case so,~~ the unit 10 then checks in a second step 24 whether the speed  $v$  of the motor vehicle 12 lies  $[[in]]$  within the interval  $I_v$ . ~~If this is the case so,~~ the unit 10 checks in a step 25 whether the speed  $v$  (Figure 1) of the motor vehicle 12 is greater than a minimum speed  $v_{min}$  and in a step 26, whether the highway upward grade  $m$  (Figure 1) is less than a maximum value  $m_{max}$ , whether a speed governing function of the motor vehicle 12 is turned off, and whether the drive unit 11 is switched on to a forward travel position. If one of the conditions checked in steps 23 - 26 is not met, in step 20

the unit 10 sets ~~in step 20~~ the control bit  $c_b$  to 0. If all of the conditions checked in steps 23 - 36 are met, the program jumps to step 19[[.]] (Figure 2).

[0027] In the constant driving mode the unit 10 uses the virtual control signal  $\alpha_{virt}$  instead of the real control signal  $\alpha$ . If [[with]] while the ~~turned-on~~ constant driving mode is turned on ( $c_b = 1$ ), in a run through the decision block 18 one of the conditions checked in the steps 23 - 26 is no longer met, in the step 20 the unit 10 ~~in the step 20~~ sets the control bit  $c_b$  and the time measurement counter to 0, [[then]] the constant driving mode is then switched off, and the phase T ends. In connection therewith, the unit 10 activates the drive unit 11 so that it is once again dependent upon the real control signal  $\alpha$ , and upon switching off the constant drive mode so that the control signal selected from the control signal  $\alpha_{virt}$ ,  $\alpha$ , dependent on [[in]] ~~which dependency~~ the unit 10 activates the drive unit 11, ~~upon switching off the constant drive mode, runs discontinuously.~~ varies with time.

[0028] The time course of the real control signal  $\alpha$  and of the virtual control signal  $\alpha_{virt}$  [[is]] based on which the unit 10 activates the drive unit 11, are shown in Figure 4, ~~in whose dependency the unit 10 activates the drive unit 11,~~ each of ~~which is~~ being represented as drawn through lines. At a point in time  $t_1$  in the step 20 the unit 10 sets the control bit  $c_b$  and the time measurement counter to 0. Thereafter, at time  $t_2$ , finally all of the conditions checked in steps 23 - 25 are fulfilled and the unit 10 increments the time measurement counter until the time duration  $\tau'$ , over which all constant driving mode conditions are met, ~~in the~~

~~time point  $\tau_2$~~  until the value  $\tau$  is reached, and ~~the unit 10~~ in the step 21 the unit 10 sets the control bit  $c_b$  to 1, the virtual control signal  $\alpha_{virt}$  to the value of the real control signal  $\alpha$  assigned to even this time point  $\tau_2$ , and the constant driving mode switched on. The phase T in which the drive unit 11 is decoupled from the real control signal  $\alpha$ , begins at time  $t_2$ . At a time ~~point~~  $t_3$  the real control signal  $\alpha$  ~~abandons~~ exceeds the interval  $I_\alpha$ , ~~so that whereby~~ the condition checked in step 23 is no longer met, and in step 20 the unit 10 ~~in step 20~~ sets the control bit  $c_b$  to 0 and switches off the constant driving mode. At the time point  $t_3$  the selected control signal  $\alpha$ ,  $\alpha_{virt}$ , dependent on which ~~stops, in whose dependency~~ the unit 10 activates the drive unit 11, ends discontinuously and jumps by a difference  $\delta$  between the virtual control signal  $\alpha_{virt}$  and the real control signal  $\alpha$ .

**[0029]**      The foregoing disclosure has been set forth merely to illustrate the invention and is not intended to be limiting. Since modifications of the disclosed embodiments incorporating the spirit and substance of the invention may occur to persons skilled in the art, the invention should be construed to include everything within the scope of the appended claims and equivalents thereof.
